**Accounting Regulations,  
Enforcement and Stock Price  
Crash Risk: Global Evidence in  
the Banking Industry**

*By Pejman Abedifar, Ming Li, Dean  
Johnson, Liang Song*

**Abstract:** This paper uses the banking industry as a unique testing setting to examine the impact of accounting and enforcement regulations on stock price crash risk. We find that stocks are less likely to crash in countries with stricter enforcement standards and accounting regulations. More importantly, we provide evidence that the impact of accounting regulations is more significant in countries with stricter enforcement standards, suggesting that enforcement mechanisms and accounting regulations are complementary. We find that the main channels for accounting regulations and enforcement standards to affect stock price crash risk are regulations that strengthen information disclosure and improve the effects of direct supervision and external auditors. Our findings are robust after we include more control variables, employ regional regulatory developments as instrumental variables, conduct change regressions, use alternative measures of enforcement, and estimate in various subsamples. Our study has policy implications about how to design accounting regulations and enforcement mechanisms in a more effective manner.

We thank Professor Kose John, Professor Iftekhar Hasan, and Professor Sudipta Basu for their valuable comments. Part of this work was performed when Liang Song was a visiting scholar at the European Central Bank, Central Bank of Finland, and Wuhan Technology and Business University, China. Part of this work was performed when Ming Li was a visiting professor at the EMLYON Business School, France. This research was supported by a Summer Research Fellowship Program grant from the Office of the Provost at the University of Massachusetts, Dartmouth, in Dartmouth, Massachusetts, USA. The authors are listed alphabetically.

## 1. Introduction

The extant literature (e.g., Ball 2009; Kothari et al. 2009) proposes that managers do not want to disclose unfavorable operating outcomes. When the cost caused by unfavorable firm-specific information is too high for managers, they could disclose all such negative information, and as a result stock prices will crash (Jin and Myers, 2006).<sup>1</sup> To solve this problem, regulatory agencies design accounting regulations to improve financial reporting quality and to reduce information risk for external investors (Bushman and Smith, 2001). Enforcement of accounting regulations is also important, because the transparency benefit gained by the adoption of high quality accounting regulations depends on the effectiveness of enforcement (Securities and Exchange Commission, 2000; Committee of European Securities Regulators, 2003). There are ample variations in enforcement mechanisms across countries, and governments are designing more enforcement regulations (e.g., Burgstahler et al., 2006; Daske et al., 2008; Landsman et al., 2012; Leuz et al., 2003; Li, 2010). However, how the benefits of accounting regulations are affected by the quality of enforcement mechanisms remains an empirical question. On the one hand, LaPorta et al. (2006) show that, unlike enforcement by private parties (private enforcement), enforcement by regulators (public enforcement) is more effective. On the other hand, Jackson and Roe (2009) find that public enforcement plays an important role.

To answer this question, we investigate whether accounting regulations and enforcement affect stock price crash risk. Crash risk is often used in the literature as an important measure of risk, because it captures “tail risk” in portfolio management (Hutton et al. 2009, Robin and Zhang 2015 among others). The stock price crash has more serious consequences when it occurs in the banking industry compared to non-finance sectors, because the crash of one bank’s stock

---

<sup>1</sup> This argument has been empirically tested in recent studies (e.g., Chen et al., 2001; DeFond et al., 2015; Hutton et al., 2009; Jin and Myers, 2006; Kim et al., 2001a,b; Kim and Zhang, 2015; Robin and Zhang, 2015).

price can result in a systemic event in the entire financial system and the macroeconomy.<sup>2</sup> The most recent example of this effect is the collapse of Lehman Brothers, which started a chain reaction in 2008. In the United States, the Federal Deposit Insurance Corporation closed 465 failed banks after the 2008 financial crisis. Thus, understanding the effects of accounting regulations and enforcement on stock price crash risk of banks would be of obvious importance to regulators and policy makers.

In addition, the banking industry provides a perfect testing ground to examine the effects of accounting regulations and enforcement mechanisms on stock price crash risk, because it enables us to consider three important aspects of enforcement regulations. These are the regulations that enhance the effective operation of market discipline, strengthen bank supervision, and improve auditing quality in the banking industry. They are customized by regulatory agencies based on the unique features of a particular industry. The importance of these regulations in banking industry is justified by the fact that they form two pillars of the Basel II and Basel III International Regulatory Frameworks (Basel Committee on Banking Supervision, 2006 and 2011). In contrast, the existing literature examining other industries (e.g., Burgstahler et al., 2006; Daske et al., 2008; Landsman et al., 2012; Leuz et al., 2003; Li, 2010) has only used the rule-of-law, which do not truly measure enforcement *per se*, as a proxy for enforcement (Brown et al., 2014). More importantly, enforcement regulations in the banking industry include both public and private enforcement (Djankov et al., 2008; La Porta et al., 2006). Therefore, our empirical tests can show the effects of both overall enforcement regulations and individual components of these regulations.

---

<sup>2</sup> Stock price crash risk is very important in risk management contexts (Robin and Zhang, 2015). It is distinct from traditional risk measurements because it captures extreme downside price movement within the tail range of the distribution, and it can be difficult to be diversified (Ibragimov and Walden, 2007).

To construct our sample, we obtain accounting regulation indicators from the World Bank surveys released in 2001, 2003, 2007, and 2011, measuring the situation of accounting regulations of 1999, 2002, 2005, and 2010 (Barth et al., 2008, 2012). We employ these indicators to explain our measurements of stock price crash risk constructed based on 2000, 2003, 2006, and 2011 data. Following the existing bank regulation literature (e.g., Barth et al., 2006; Tadesse, 2006), the accounting regulation variable is defined as the sum of answers to six survey questions, such as whether banks are required to report off-balance sheet items. We measure enforcement based on regulations that increase audit quality, regulations that strengthen market discipline, and regulations that depend on direct supervision. Following the previous literature (Chen et al., 2001; Kim et al., 2001a,b; Jin and Myers, 2006; Hutton et al., 2009; DeFond et al., 2015; Kim and Zhang, 2015; Robin and Zhang, 2015), we employ two measurements as proxies for stock price crash risk. The first measurement is the negative skewness of bank-specific returns. The second measurement is the relative volatility of down- to up-week bank-specific returns.<sup>3</sup>

Employing a sample of observations that includes 37 countries, we provide robust evidence that stocks have less crash risk in countries with better accounting and enforcement regulations. The results suggest that stricter accounting and enforcement regulations could mitigate managers' bad news hiding behavior and reduce stock price crash risk (Chen et al., 2001; Kim et al., 2001a,b; Jin and Myers, 2006; Hutton et al., 2009; DeFond et al., 2015; Kim and Zhang, 2015; Robin and Zhang, 2015). In addition and more importantly, we provide evidence

---

<sup>3</sup> We also construct two other stock price crash risk measures following the existing literature (Chen et al., 2001; DeFond et al., 2015; Hutton et al., 2009; Jin and Myers, 2006; Kim et al., 2001a,b; Kim and Zhang, 2015; Robin and Zhang, 2015) and use them as the robustness tests. The third measure is *Crash Indicator*, which equals one if at least one of a bank's bank-specific weekly returns in a given year is 3.09 standard deviations below the mean value. The fourth measure is *Crash Frequency*, which is constructed as the difference between the frequency of negative stock return outliers and the frequency of positive stock return outliers. Negative or positive stock return outliers are defined as the residual from Equation (1), which are lower than 1 percent of the distribution or higher than 99 percent of the distribution. This variable is presented in percentage. Higher values mean more stock price crash risk. We still obtain the same conclusion in untabulated results.

that the effects of accounting regulations are more significant in countries with stricter enforcement standards. The results suggest that accounting regulations and enforcement are complements, and both determine the likelihood of stock crash.

In our baseline test, our accounting regulations and enforcement variables include multiple dimensions of regulations. We also attempt to identify the effects of specific regulations. We find that most of the financial reporting regulations contribute to lower stock price crash risk. We also show that enforcement regulations that strengthen the effects of external audit and direct supervision are more effective in determining stock price crash risk. Our results are robust even after including a series of control variables, for both large banks and small banks subsamples, for the subsample without U.S. banks, and when we employ alternative measures of enforcement.

We conduct a number of tests to address the endogeneity concerns. First, we regress changes in stock price crash risk against changes in accounting regulations and enforcement, as well as changes in other control variables. Second, we employ regional trends in accounting regulations and enforcement as our instruments to conduct an instrumental variable estimation. Our results of change regression and instrumental variable estimation essentially produce the same inferences. Finally, we show that the effects of accounting and enforcement regulations are more significant in countries with high institutional quality. If our accounting regulations and enforcement variables only capture the omitted variables, we cannot find such results. Thus, the results suggest that our baseline results are less likely biased by endogeneity problems.

Our findings are crucial for several reasons. First, we contribute to the existing enforcement literature examining business firms (e.g., Burgstahler et al., 2006; Daske et al., 2008; Landsman et al., 2012; Leuz et al., 2003; Li, 2010). Specifically, their enforcement measurements, such as rule of law, do not truly measure enforcement *per se* (Brown et al., 2014).

Different from these studies, we use the banking industry as a unique setting to test the effects of enforcement because enforcement in this highly regulated industry is entirely customized by regulatory agencies and all industry-specific regulations. Our study could provide new insights into the effects of enforcement regulations.

More importantly, bank regulatory and supervisory authorities such as the International Monetary Fund and the World Bank promote private enforcement regulations because they believe that these regulations play a more important role (LaPorta et al., 2006). However, Jackson and Roe (2009) show that public enforcement regulations are also effective. In our paper, the measure of the enforcement regulations includes both regulations that strengthen both private and public enforcement. We demonstrate that the main effects of enforcement regulations on stock price crash risk are from enforcement regulations that strengthen external audit and direct supervision. Therefore, we contribute to the debate about the effectiveness of public and private enforcement.

Second, we contribute to the literature about the determinants of stock price crash risk (e.g., An and Zhang 2013; Francis et al., 2015; Hamm et al., 2012; Kim et al., 2011a, b; Kim and Zhang, 2015; Kim et al., 2016; Robin and Zhang, 2015).<sup>4</sup> Our findings suggest that accounting regulations and enforcement can significantly reduce stock price crash risk and these two dimensions of regulations are complements in affecting stock price crash risk. Thus, our results provide an additional view about how to reduce stock price crash risk and thereby to contribute

---

<sup>4</sup> The existing literature (An and Zhang 2013; Francis et al., 2015; Hamm et al., 2012; Kim et al., 2011a, b; Kim and Zhang, 2015; Kim et al., 2016; Robin and Zhang, 2015) has shown that tax avoidance activities, CFOs' option incentives, institutional ownership, management forecasts, accounting conservatism, audit quality, CEO overconfidence, and real earnings management are significantly associated with stock price crash risk. Related to our study, Haggard et al. (2008) find that business firms with more voluntary disclosure have lower stock crash risk. Hutton et al. (2009) show that business firms with more transparent financial statements are less likely to crash in terms of their stocks. Extending the idea to the country level, Jin and Myers (2006) find that business firms' stocks are more likely to crash in countries with fewer auditors and poor financial statement disclosure. Bleck and Liu (2007) claim that if a historical-cost accounting regime is more opaque, there is a greater stock price crash risk. DeFond et al. (2015) find that the adoption of IFRS reduces stock price crash risk for non-financial firms and selectively influences financial firms.

to the development of the whole economy. Additionally, Defond et al (2015) indicate that little is known about the determinants of crash risk for financial firms. Our paper fills the void by using more precise variables than those of previous studies.

Finally, our study contributes to the literature about the effects of bank accounting regulations. Specifically, Tadesse (2006) shows that stricter bank disclosure regulations can decrease the likelihood of a financial crisis. Barth et al. (2006) and Granja (2014) find that high quality bank accounting regulations can enhance the stability of the financial system. Duru et al. (2018) claim that high quality bank accounting regulations can increase financial statement informativeness. Song (2017) shows that quality of bank accounting regulations is positively related to stock return and is negatively associated with stock volatility. We extend the literature by investigating whether stricter bank accounting regulations affect stock price crash risk, which is distinct from traditional risk measurements, and is not easy to be diversified (Ibragimov and Walden, 2007). Our findings also provide important channels to explain these results in the existing literature, and therefore, have important policy implications for regulatory agencies.

The remainder of the research is organized thusly. Section 2 develops the hypotheses. Section 3 presents the data. Section 4 describes the empirical results. Section 5 makes the conclusion.

## **2. Hypothesis Development**

Our aim is to contribute to an understanding of how the quality of accounting standards and enforcement mechanisms affect stock price crash risk of commercial banks. Crash risk is often regarded as a proxy for “tail risk” in portfolio management and hence is one of the important risk measures for investors (Hutton et al. 2009; Robin and Zhang 2015). Crash risk is

more prevalent for commercial banks for a number of reasons: first, banks tend to be more opaque than non-financial firms and opacity can intensify crash risk (Bleck and Liu 2007). Banks' assets consist of a pool of loans to thousands of borrowers and can be easily transformed, given that banks continuously generate new assets from the installments they receive from the outstanding loans (Flannery 1994). Morgan (2002) empirically tests the opacity of banks by showing that they are more likely than non-financial firms to carry split ratings. Second, banks are highly leveraged and suffer from structural asset-liability mis-match, because they transform illiquid assets (loans) to liquid liabilities (demand deposits) (Diamond and Dybvig 1983). Hence, the structural fragility of commercial banks make them subject to severe crash risk. Third, the crash risk in the banking system can impose a substantial negative externalities to the economy, because banks are highly interconnected and as a result a shock to one bank can be transmitted to other banks, which can cause a contagion in the whole market (Rochet and Tirole 1996; Allen and Gale 2000).

In order to achieve our objective, we test the following three hypotheses:

*Hypothesis 1:* Stricter bank accounting regulations reduce stock price crash risk.

*Hypothesis 2:* Stricter enforcement regulations reduce stock price crash risk.

*Hypothesis 3:* The impact of bank accounting regulations is more significant in countries with stricter enforcement.

First, the existing literature shows that stricter accounting regulations can restrain management from manipulation of financial reports (Barth, et al. 2008) and thereby increases reliability of disclosed information. Moreover, it can push the managers to provide more comprehensive information to outsiders (Bushman and Smith, 2001; Ewert and Wagenhofer, 2005) which leads to stronger market discipline and timely intervention of outsiders to correct

the flaws in the managerial system. We expect that stricter accounting regulations is particularly important for reducing stock price crash risk, given that managers have incentives to hide bad news from the public in order to avoid receiving blames from various stakeholders (Chen et al., 2001; Kim et al., 2001a, b; Jin and Myers, 2006; Hutton et al., 2009; DeFond et al., 2015; Kim and Zhang, 2015; Robin and Zhang, 2015).

Second, stock price crash risk also depends on effectiveness of enforcement mechanisms of accounting standards. Compliance with accounting standards can be promoted via effective market discipline, direct supervision and audit services.<sup>5</sup> Specifically, enforcement regulations, which improve market discipline, not only can allow market participants to directly influence managers' behaviors but can also provide market signals to regulators to trigger regulatory intervention (e.g., Rochet, 2005; Stephanou, 2010). Enforcement regulations, which are related to direct supervision, require that financial reporting behaviors of managers be consistent with accounting regulations (Beck et al., 2006; Barth et al., 2004; Demirgüç-Kunt et al., 2008).<sup>6</sup> Enforcement regulations, which strengthen audit services, can ensure financial reporting quality (Ball et al., 2003; Hope, 2003).<sup>7</sup> The discussion suggests that stricter compliance with accounting standards is expected to make stock price crash less likely by confining the managerial excessive risk taking behavior, reducing the possibility of accounting manipulation and also improving the quality of financial reports. . Yet, one may argue that regulations that increase private monitoring by external investors and auditors may be not able to impose severe punishments on wrongdoers. Regulators, who implement public enforcement, may not have enough information about the

---

<sup>5</sup> Brown et al. (2014) define enforcement as “the activities undertaken by independent bodies (monitoring, reviewing, educating, and sanctioning) to promote firms’ compliance with accounting standards in their statutory financial statements.”

<sup>6</sup> This argument has been shown in the existing empirical evidence (e.g., Barth et al., 2004; Beck et al., 2006; Demirgüç-Kunt et al., 2008).

<sup>7</sup> Consistent with this notion, Francis et al. (2003) and Sami and Zhou (2008) find that a better audit environment is associated with superior financial reporting quality.

market (Jackson and Roe, 2009). Therefore, these enforcement regulations may not play a very important role.

Third and importantly, we investigate whether enforcement mechanisms complement or substitute accounting regulations in ameliorating stock price crash risk. There are two reasons why enforcement mechanisms complement accounting regulations. On the one hand, enforcement mechanisms play a very crucial role, because without adequate enforcement, managers have no incentive to comply with accounting regulations (e.g., Burgstahler et al., 2006).<sup>8</sup> On the other hand, the effectiveness of enforcement mechanisms depends on the quality of accounting regulations (e.g., Tadesse, 2006; Demirgüç-Kunt et al., 2008; Bushman and Williams, 2012). Thus, the influence of laying down high quality accounting regulations might be more significant in countries with stricter enforcement mechanisms. It is also possible that enforcement mechanisms and accounting regulations could be substitutes because they can both contain managers' bad news hiding behaviors and increase financial reporting quality (e.g., La Porta et al., 1998; Hope, 2003). Thus, the impact of establishing efficient accounting standards might be less significant in countries with stricter enforcement environments.

### **3. Data**

#### **3.1. Variable Construction**

In this section, we describe the details of the variable construction, also shown in table 1. Specifically, we use the variables *Accounting Regulation* and *Enforcement* to measure the following regulations: the financial statement transparency and the effectiveness of enforcement.

---

<sup>8</sup> Consistent with this argument, the existing literature (e.g., Byard et al., 2011; Daske et al., 2008; Li, 2010) finds that the adoption of IFRS can reduce earnings management, decrease the cost of capital, increase stock liquidity, and improve firm valuation. These beneficial effects of IFRS are stronger in countries with better enforcement.

Following the existing bank regulation literature (e.g., Barth et al., 2006; Tadesse, 2006), we obtain these indicators from the World Bank surveys. The variable *Accounting Regulation* is defined as the sum of answers to six survey questions, such as whether banks are required to report off-balance sheet items (Barth et al., 2006). The variable *Enforcement* is equal to the sum of the three variables *External Audit*, *External Monitoring*, and *Direct Supervision*. The variable *External Audit* is equal to the sum of answers to seven survey questions, such as whether supervisors can sue external auditors and force them to report directly to the regulators about the misconduct of bank managers. The variable *External Monitoring* is measured as the sum of answers to five survey questions, such as whether the bank is rated. The variable *Direct Supervision* equals the sum of answers to ten survey questions, such as whether the authorities can establish a new internal organizational structure of a bank.

In this study, we employ two measures of crash risk. We follow the previous literature (e.g., Chen et al. 2001; Kim et al. 2011a & b; DeFond et al., 2015) and use *Negative Skewness* as the first measure. The *Negative Skewness* is defined as the negative of the third moment of bank-specific weekly returns, hereinafter  $W_{i,t}$ , for each sample year, divided by the standard deviation of  $W_{i,t}$  raised to the power of three, i.e. minus skewness of  $W_{i,t}$ . Since a negatively skewed distribution demonstrates the risk of extreme downside returns, we multiply the skewness by minus one for the ease of interpretation, e.g. a higher number indicates a greater crash risk.

For our second measure of crash risk, we follow Chen et al. (2001) and Kim et al. (2011a) and use the *Down Up Volatility*. To calculate this measure, we construct two subsamples. The first one consists of the weeks with the  $W_{i,t}$  below the yearly average, hereinafter down weeks subsample. In the second subsample, we include the weeks with the  $W_{i,t}$  above the yearly average, hereinafter up weeks subsample. Next, we calculate the standard deviation in each of

the two subsamples. Then, we compute the ratio of the standard deviation in the down weeks subsample to the standard deviation in the up weeks subsample. The *Down Up Volatility* is defined as the natural logarithm of this ratio. A higher value of this variable indicates a greater stock price crash risk.

We compute  $W_{i,t}$  as the natural logarithm of one plus the residual return of the below expanded market model, which is used in the previous studies (e.g. DeFond et al. 2015):

$$\begin{aligned}
 R_{i,t} = & \alpha_i + \beta_{1,i} R_{m,j,t} + \beta_{2,i} [R_{US,t} + Ex_{j,t}] + \beta_{3,i} R_{m,j,t-1} + \beta_{4,i} [R_{US,t-1} + Ex_{j,t-1}] + \beta_{5,i} R_{m,j,t-2} + \beta_{6,i} \\
 & [R_{US,t-2} + Ex_{j,t-2}] + \beta_{7,i} R_{m,j,t+1} + \beta_{8,i} [R_{US,t+1} + Ex_{j,t+1}] + \beta_{9,i} R_{m,j,t+2} + \beta_{10,i} [R_{US,t+2} + Ex_{j,t+2}] + \\
 & \varepsilon_{i,t}
 \end{aligned} \tag{1}$$

The variable  $R_{i,t}$  is equal to the Wednesday-to-Wednesday weekly return on stock  $i$ . We only include bank stocks with more than 30 weeks of data in a certain year and countries with at least two banks. The variable  $R_{m,j,t}$  is equal to the weekly return of the market index in country  $j$ . The variable  $R_{US,t}$  equals the U.S. market return. The variable  $Ex_{j,t}$  is the change in the exchange rate between country  $j$  and the U.S. When we calculate the stock price crash risk measurements in the U.S. market,  $\beta_{2,i}$ ,  $\beta_{4,i}$ ,  $\beta_{6,i}$ ,  $\beta_{8,i}$  and  $\beta_{10,i}$  are equal to zero.

We construct a series of country-level control variables based on data from the World Bank surveys. Specifically, the variable *Accounting Standards* is equal to one if a country's accounting standard is IFRS or U.S. GAAP and zero otherwise. The variable *Activity Restriction* is constructed as the sum of answers to three survey questions, such as whether banks are allowed to conduct business activities in the areas of real estate, insurance, and securities. Higher

values of this variable indicate more restrictiveness. We employ the variable *Capital Stringency* to measure the level of capital stringency.

We use the variable *Democracy Quality* to measure the level of democracy of a country, which is constructed as a revised combined polity score from the Polity IV Project. This polity score is widely used in political science research.<sup>9</sup> This variable has a value from -10 to +10. The lowest value -10 indicates that a country is strongly autocratic and the highest value +10 indicates that a country is strongly democratic. We also obtain data from the World Development Indicator database to define the variables *GDP Per Capita* and *GDP Growth*, which measure the situation of economic development and growth, respectively.

We construct several control variables to measure stock characteristics based on data from the Datastream database following the existing literature (Chen et al., 2001; DeFond et al., 2015; Hutton et al., 2009; Jin and Myers, 2006; Kim et al., 2001a,b; Kim and Zhang, 2015; Robin and Zhang, 2015). Specifically, the variable *Share Turnover* equals the difference in the average monthly bank stock share turnover between the current year and the prior year, in which monthly bank stock share turnover is defined as the monthly bank stock trading volume scaled by the number of bank stock shares outstanding during the month. The variable *Deviation of Return* is defined as the standard deviation of bank-specific weekly returns in a given year. The variable *Mean of Return* is equal to the mean value of bank-specific weekly returns in a given year.

We also construct a series of bank-level control variables based on data from the Bankscope database. Specifically, the variable *Bank Total Assets* is equal to the logarithm of a bank's total assets. The variable *STD ROA* equals the standard deviation of a bank's ROAs over the prior five-year period. The variable *Nonperforming Loan* is defined as a bank's total problem

---

<sup>9</sup> More details can be found in the website <http://www.systemicpeace.org/polity/polity4.htm>

loans divided by total assets. In addition, we construct the variable *Analyst* based on data from the IBES database, which is measured as the number of analysts with earnings forecasts for a certain bank.

(Insert Table 1 about here)

### 3.2. Sample and Summary Statistics

To construct our sample, we obtain accounting regulation indicators from the World Bank surveys released in 2001, 2003, 2007, and 2011, measuring the situation of accounting regulations at the end of 1999, 2002, 2005, and 2010 (Barth et al., 2008, 2012). We employ these indicators to explain our measurements of stock price crash risk constructed based on 2000, 2003, 2006, and 2011 data. Our sample includes 1,711 observations from 37 countries across four years. The banks in the sample have more than 90% of the total assets of the global banking industry.

Panel A of table 2 presents the number of banks, number of observations, and average value of our accounting regulation variables by country. For example, the mean values of the variable *Enforcement* in the United States have the highest value of 20.375. The average values of the variable *Accounting Regulation* has the highest value of 6 in South Korea and South Africa. The results indicate that the level of regulatory developments is different across countries. In untabulated results, the mean values of the variable *Enforcement* in 1999, 2002, 2005, and 2010 are 14.94, 16.50, 16.93, and 17.17 respectively. The average values of the variable *Accounting Regulation* in 1999, 2002, 2005, and 2010 are 4.50, 5.12, 5.40, and 5.53 respectively. The results suggest that the levels of accounting regulation and enforcement are increasing over

time as they might do in response to these two crises (Asian Financial Crisis and Global Financial Crisis).

(Insert Table 2 about here)

Panel B of table 2 shows summary statistics of variables in the entire sample. These results are consistent with the findings provided by the existing literature. Specifically, the dependent variable *Negative Skewness* has a mean value of -0.275 and a standard deviation of 0.600. The average value of the other dependent variable, *Down Up Volatility*, is -0.141 and has a standard deviation of 0.500. The key variable *Accounting Regulation* has a mean value of 5.193 and a standard deviation of 0.751. The other key variable *Enforcement* has an average value of 16.559 and a standard deviation of 2.806. The results suggest that there is sufficient variation in the variables employed in our empirical tests.

Panel C of table 2 describes the correlations among our country-level variables. The correlation coefficient between *Accounting Regulation* and *Enforcement* is 0.189. The results suggest that a country with stronger accounting regulations might not have the same level of enforcement. We also find that these two key variables do not have strong correlations with our country-level control variables. Therefore, our estimations are not biased by multicollinearity problems.

## **4. Results**

### **4.1. Univariate Analysis**

Table 3 describes the results of our univariate analysis. In panels A and B, we test the effects of accounting regulations and enforcement on stock price crash risk. Specifically, we create two subsamples. In the “high” subsample, as presented in the second column, the variables

*Accounting Regulation* and *Enforcement* have values greater than the sample median. In the “low” subsample, as presented in the third column, the variables *Accounting Regulation* and *Enforcement* have values less than the sample median. We report the average value of *Negative Skewness* and *Down Up Volatility* in these two subsamples and the differences in the last column.

(Insert Table 3 about here)

As reported in panel A, the average value of the variable *Negative Skewness* is equal to -0.335 in countries with stricter regulations on the effectiveness of enforcement. The mean value of the variable *Negative Skewness* is equal to 0.042 in countries with lower levels of regulations on the effectiveness of enforcement. The average value of the variable *Negative Skewness* is equal to -0.314 in countries with stricter regulations on the transparency of financial statement disclosure. The average value of the variable *Negative Skewness* equals 0.657 in countries with lower level of regulations on the transparency of financial statement disclosure. We obtain the same results for *Down Up Volatility* in panel B. The differences between these two subsamples as presented in the last column are all statistically significant at the 1% level. These results suggest that stocks have less crash risk in countries with stricter accounting and enforcement regulations.

As reported in panels C and D, we further split our sample into four 2×2 groups based on the variables *Accounting Regulation* and *Enforcement*. As described in panel C, the difference in *Negative Skewness* between a high accounting regulation regime and a low accounting regulation regime is 0.238 when a country has low enforcement standards. The difference in *Negative Skewness* between a high accounting regulation regime and a low accounting regulation regime is 0.279 when a country has high enforcement standards, which is statistically significant at the 10% level. We obtain the same results for *Down Up Volatility* in panel D. The results suggest

that the effects of accounting regulations on stock price crash risk are more pronounced in a country with high enforcement standards.

## 4.2. Multivariate Analysis

### 4.2.1. Baseline Regressions

To examine the effects of accounting regulations and enforcement standards on stock price crash risk, we estimate the following baseline equation:

$$\begin{aligned} \text{Negative Skewness or Down Up Volatility} = & \alpha + \beta_1 \text{Accounting Regulation} + \beta_2 \text{Enforcement} + \beta_3 \\ & \text{Control variables} + \text{Year effects} + \varepsilon \end{aligned} \quad (2)$$

We have two key variables: *Accounting Regulation* and *Enforcement*. We expect that these two variables have negative impacts on stock price crash risk. We include several country-level regulation, governance and economic development variables. Specifically, we control for *Accounting Standards*, *Activity Restriction*, *Capital Stringency*, *Democracy Quality*, *GDP Per Capita*, and *GDP Growth*. We expect that these variables might be negatively associated with stock price crash risk following the existing literature (e.g., DeFond et al., 2015; Hutton et al., 2009; Jin and Myers, 2006; Kim et al., 2001a, b; Kim and Zhang, 2015; Robin and Zhang, 2015).

We also include several bank characteristics. Specifically, we control for the variables *Bank Total Assets*, *STD ROA*, *Nonperforming Loan*, and *Analyst*, which are related to banks' risk and information environments. Finally, we include some variables to measure stock characteristics, such as *Negative Skewness* in the previous year, *Share Turnover*, *Deviation of Return*, and *Mean of Return* because these variables could be positively associated with stock

price crash risk following the prior literature (DeFond et al., 2015; Hutton et al., 2009; Jin and Myers, 2006; Kim et al., 2001a, b; Kim and Zhang, 2015; Robin and Zhang, 2015). Compared to the dependent variables, all of the independent variables are measured in the previous year. In the estimations, we include year fixed effects and cluster by countries. The regression coefficients in all tables are unstandardized. We do not report constant for brevity.

More importantly, we investigate whether the impact of accounting regulations are more significant in countries with stricter enforcement mechanism. Compared to equation (3), we include an interaction term between *Accounting Regulation* and *Enforcement*. We expect the coefficient of this interaction term to be statistically negative. Specifically, we estimate the following equation:

$$\begin{aligned} \text{Negative Skewness or Down Up Volatility} = & \alpha + \beta_1 \text{Accounting Regulation} \times \text{Enforcement} + \beta_2 \\ & \text{Accounting Regulation} + \beta_3 \text{Enforcement} + \beta_4 \text{Control variables} + \text{Year effects} + \varepsilon \end{aligned}$$

(3)

Columns (1) and (2) of table 4 present multivariate analysis of the influence of accounting and enforcement regulations on stock price risk measured by *Negative Skewness*. In Columns (1), we include country fixed effects, and we do not include country-level control variables. The coefficients of *Accounting Regulation* and *Enforcement* are all negative and statistically significant at the 1% level. These results are robust when we include county-level and bank-level control variables. The results suggest that stocks are less likely to crash in countries with better accounting and enforcement regulations. We also find that banks with higher non-performing loan and share turnover have higher stock price crash risk. The

coefficients of the variables *Democracy Quality* and *Accounting Standards* are negative and statistically significant at 1% level, implying that superior institutional environment and higher accounting standards can reduce banks' risk taking behaviors.

Based on the results reported in column (2) of table 4, a one-standard-deviation increase in the variable *Accounting Regulation* (0.751) reduces the variable *Negative Skewness* by 0.204 ( $=0.272 \times 0.751$ ). This would reduce the average *Negative Skewness* from -0.275 to -0.479, and the median *Negative Skewness* from -0.376 to -0.580. This shift is about 16.3% ( $=0.204/1.250$ ) of the range (1.250) between the 10th percentile (-0.853) and 90th percentile (0.397). A one-standard-deviation increase in the variable *Enforcement* reduces the variable *Negative Skewness* by 0.191 ( $=0.068 \times 2.806$ ). This would reduce the average *Negative Skewness* from -0.275 to -0.466, and the median *Negative Skewness* from -0.376 to -0.567. This shift is about 15.3% ( $=0.191/1.250$ ) of the range (1.250) between the 10th percentile (-0.853) and 90th percentile (0.397). Thus, our findings are also economically significant.

(Insert Table 4 about here)

Columns (4) and (5) of table 4 present multivariate analysis of the influence of accounting and enforcement regulations on bank stock price crash risk measured by *Down Up Volatility*. In Columns (4), we include country fixed effects because we do not include country-level control variables. The coefficients of *Accounting Regulation* and *Enforcement* are all negative and statistically significant at the 1% level. We obtain the same conclusion when we include county-level and bank-level control variables. The results indicate that stocks have less crash risk in countries with stricter regulations on the effectiveness of enforcement and transparency of financial statements practices.

Based on the results reported in column (5) of table 4, a one-standard-deviation increase in the variable *Accounting Regulation* (0.751) reduces the variable *Down Up Volatility* by 0.240 ( $=0.319 \times 0.751$ ). This would reduce the average *Down Up Volatility* from -0.500 to -0.740, and the median *Down Up Volatility* from -0.223 to -0.463. This shift is about 19.7% ( $=0.240/1.217$ ) of the range (1.217) between the 10th percentile (-0.744) and 90th percentile (0.473). A one-standard-deviation increase in the variable *Enforcement* (2.806) reduces the variable *Down Up Volatility* by 0.154 ( $=0.055 \times 2.806$ ). This would reduce the average *Down Up Volatility* from -0.500 to -0.654, and the median *Down Up Volatility* from -0.223 to -0.377. This shift is about 12.7% ( $=0.154/1.217$ ) of the range (1.217) between the 10th percentile (-0.744) and 90th percentile (0.473). Thus, our findings are also economically significant.

Columns (3) and (6) of table 4 presents multivariate analysis of the influence of the interaction between accounting and enforcement regulations on stock price crash risk measured by *Negative Skewness* and *Down Up Volatility*. The coefficients of the interaction term between *Accounting Regulation* and *Enforcement* are all negative and statistically significant at the 1% or 10% level. Our results suggest that regulations on the transparency of financial statement disclosure might be less enforceable without stricter regulations on the strength of enforcement (Knechel et al., 2013). Stricter enforcement mechanisms should assure the quality of banks' financial disclosures by deterring earning misstatements. Thus, enforcement mechanisms and accounting regulations are complements in determining the likelihood of stock crashes.

In summary, our results suggest that stricter accounting regulations can push managers to provide more relevant information to outside investors (Bushman and Smith, 2001; Ewert and Wagenhofer, 2005). Stricter enforcement, such as market discipline, direct supervision, and audit services, might better monitor managers' opportunistic behaviors. Thus, stricter accounting

regulations and enforcement could alleviate bad-news hoarding and decrease stock price crash risk.

#### **4.2.2. Individual Impacts of Accounting and Enforcement Regulations**

In the above empirical tests, our accounting regulations and enforcement variables include multiple dimensions of regulations. In this section, we attempt to identify specific regulations affecting stock price crash risk. As shown in panel A of table 5, we construct six dummy variables -- *SQ1*, *SQ2*, *SQ3*, *SQ4*, *SQ5*, and *SQ6* -- with the six survey questions, which are employed to construct the variable *Accounting Regulation*. The results show that five of the six dummy variables are negatively associated with stock price crash risk. The results suggest that the first financial reporting requirement based on the first survey question (*SQ1*) is not significantly related to stock price crash risk.<sup>10</sup> We also construct six interaction terms between these six dummy variables and *Enforcement*. The results still show that the five interaction terms with these five dummy variables are significant for determining stock price crash risk. In summary, most of these financial reporting regulations contribute to lower stock price crash risk.

(Insert Table 5 about here)

Similarly, as shown in panel B of table 5, we include three variables -- *External Audit*, *External Monitoring*, and *Direct Supervision* -- which are employed to create the variable *Enforcement*. The results show that the coefficients of *External Audit* and *Direct Supervision* are statistically significant and are negatively associated with stock price crash risk. We also construct three interaction terms between these three enforcement variables and *Accounting Regulation*. We obtain similar results, suggesting that enforcement regulations that strengthen

---

<sup>10</sup> The first survey question is “Does accrued, though unpaid interest/principal, enter the income statement while the loan is still performing?” Barth et al. (2006).

the effects of external audits and direct supervision are more effective in determining stock price crash risk.

### 4.2.3. Endogeneity Tests

In this section, we attempt to address potential endogeneity problems. First, we conduct a change regression. As reported in panel A of table 6, we regress changes in stock price crash risk ( $\Delta$ *Negative Skewness* and  $\Delta$ *Down Up Volatility*) against changes in accounting regulations and enforcement ( $\Delta$ *Accounting Regulation* and  $\Delta$ *Enforcement*), as well as changes in other control variables. We find that the coefficients of the variables  $\Delta$ *Accounting Regulation* and  $\Delta$ *Enforcement* are significantly negative. The results suggest that changes in accounting regulations and enforcement standards drive changes in stock price crash risk. As shown in columns (2) and (4), we find that the coefficients of the interaction term between  $\Delta$ *Accounting Regulation* and  $\Delta$ *Enforcement* are also significantly negative.

Second, we conduct a two-stage instrumental variable estimation. Specifically, we define two instrument variables (*Avg Accounting Regulation* and *Avg Enforcement*) as the average values of accounting regulations (enforcement regulations) in an area where a bank is located.<sup>11</sup> We believe that region-level regulatory developments will definitely influence the regulation developments of each country. However, region-level regulatory developments will not directly affect stock price crash risk of each bank.<sup>12</sup>

The results of the two-stage instrumental variables estimation are presented in panel B of table 6. In columns (1) and (2), we report the results of the first stage regression. In the first stage

---

<sup>11</sup> When we calculate the average values, we exclude the bank's own country. We follow the World Bank's classification, and define seven regions: East Asia and the Pacific; South Asia; Middle East and North Africa; Africa; Eastern Europe and Central Asia; Western Europe and other developed counties; and Latin America and the Caribbean.

<sup>12</sup> For the use of similar instrumental variables, please see Acemoglu et al. (2015).

regression, we regress *Accounting Regulation (Enforcement)* against our instrumental variables, *Avg Accounting Regulation* and *Avg Enforcement*, as well as other country-level variables and country and year dummy variables. The results show that the coefficients of our instrumental variables are significantly positive at the 1% level, suggesting that our instrumental variables are valid. In columns (3) and (5), we report the results of the second-stage regressions. In the second-stage regressions, we include the predicted values of our accounting regulations and enforcement variables, *Fitted Accounting Regulation* and *Fitted Enforcement*, from the first stage. In columns (4) and (6), we further add the interaction term between *Fitted Accounting Regulation* and *Fitted Enforcement*. The results are similar to our findings using the baseline model, as presented in table 4.

Finally, we add the interaction terms *Accounting Regulation*  $\times$  *Democracy Quality* and *Enforcement*  $\times$  *Democracy Quality* to our baseline model in table 4. We believe that, if our accounting regulations and enforcement variables only capture the omitted variables, we cannot find that the effects of these two variables are more significant in countries with high intuitional quality. As shown in panel C of table 6, the coefficients of these two interaction terms are negative and statistically significant at the 1% level. The results suggest that our baseline results are less likely biased by endogeneity problems.

(Insert Table 6 about here)

### **4.2.3. Robustness Tests**

In this section, we estimate our baseline regression using alternative specifications. First, as shown in the recent financial crisis, large banks have more possibility to be bailed out by the government. Thus, there might be structural differences between large banks and small banks. To

ensure that our baseline results are not biased by bank size, we split our sample into a large bank subsample and a small bank subsample based on the median value of the variable *Bank Total Assets*. As shown in table 7, we still obtain the same conclusion in the subsamples as those in table 4.

(Insert Table 7 about here)

Second, in our baseline test, we define our enforcement variable as the sum of *External Audit*, *External Monitoring*, and *Direct Supervision*. To ensure that our enforcement variable is a valid measurement, we employ two alternative measurements of enforcement standards: *External Audit & Direct Supervision* and *Direct Supervision*. The variable *External Audit & Direct Supervision* is equal to the sum of *External Audit* and *Direct Supervision*. As shown in Table 8, our results remain the same as in table 4. Finally, we test whether our results still hold in the subsample without U.S. banks because 41% of our sample banks are U.S. banks and it might bias our estimations. We still obtain the same conclusions as in table 4 in untabulated results.

(Insert Table 8 about here)

We also construct two other stock price crash risk measures following the existing literature (Chen et al., 2001; DeFond et al., 2015; Jin and Myers, 2006; Kim et al., 2001a,b; Kim and Zhang, 2015; Robin and Zhang, 2015) and use them as the robustness tests. The third measure is *Crash Indicator*, which equals one if at least one of a bank's bank-specific weekly returns in a given year is 3.09 standard deviations below the mean value. The fourth measure is *Crash Frequency*, which is constructed as the difference between the frequency of negative stock return outliers and the frequency of positive stock return outliers. Negative or positive stock return outliers are defined as the residual from Equation (1), which are lower than 1 percent of the distribution or higher than 99 percent of the distribution. This variable is presented in

percentage. Higher values mean more stock price crash risk. We still obtain the same conclusion in untabulated results.

Our data cover the years 2000, 2003, 2006 and 2011. These four years cover very different economic circumstances such as Asian Financial Crisis and Global Financial Crisis, which may bias our estimation. To address this concern, we report the results in the subsample across years (2000, 2003, 2006 and 2011). We still obtain the same conclusion in untabulated results.

## **5. Conclusion**

Regulatory agencies design accounting regulations to improve financial reporting quality and to reduce information risk for external investors (Bushman and Smith, 2001). Enforcement of accounting regulations is also important, because the benefits of adopting high quality accounting regulations will be realized when we establish an effectiveness enforcement mechanism (Securities and Exchange Commission, 2000; Committee of European Securities Regulators, 2003). Employing a sample including major banks from 37 countries as a unique testing ground, we find that stocks are less likely to crash in countries with better enforcement mechanisms and accounting regulations. More importantly, we provide evidence that the impact of accounting regulations is more significant in countries with stricter enforcement standards. Thus, enforcement standards and accounting regulations are complements and both determine the likelihood of stock price crashes. We also find that the main channels for enforcement standards and accounting regulations to affect stock price crash risk are regulations that strengthen information disclosure and improve the effects of direct supervision and external auditors.

Our findings have significant policy implications. The information that we provide could help design more effective accounting regulations and enforcement mechanisms. For example, to increase transparency and financial stability, regulators could increase strictness in either enforcement mechanism or disclosure requirements. The effects are more significant when the strictness of both accounting regulations and enforcement are increased. In addition, regulations could strengthen information disclosure and improve the effects of direct supervision and external auditors.

As in pretty much every other study in this area, our results are associational rather than causal. Future study may examine the causality of the relationship between these regulations and stock price crash risk. Future research could also investigate how accounting regulations and enforcement standards determine accounting conservatism. Another avenue is to examine how accounting regulations and enforcement mechanisms help increase stock price informativeness. We leave these potential research areas for further research.

**Table 1. Variable Definitions**

<b>Variable</b>	<b>Description</b>
<b>Dependent variables</b>	
Negative Skewness	The negative skewness of bank-specific weekly returns. Bank-specific weekly return is equal to the natural logarithm of the sum between the residual from Equation (1) and one.
Down Up Volatility	Log (the standard deviation of bank-specific returns in down weeks divided by the standard deviation of bank-specific weekly returns in up week).
<b>Accounting regulation variables</b>	
Accounting Regulation	“The sum of assigned values of the questions as below (by default, 1 if it equals “yes” and 0 otherwise.): (1) Does accrued, though unpaid interest/principal enter the income statement while the loan is still performing? (2) Are financial institutions required to produce consolidated accounts covering all bank and any nonbank financial subsidiaries? (3) Are off-balance sheet items disclosed to the public? (4) Must banks disclose their risk management procedures to the public? (5) Are bank directors legally liable if information disclosed is erroneous or misleading? (6) Does accrued, though unpaid interest/principal enter the income statement while the loan is still nonperforming? (1 if it is No; 0 otherwise.) Higher values indicate greater financial statement transparency.” Barth et al., (2006).
External Audit	“The sum of assigned values of the questions as below (by default, 1 if it equals “yes” and 0 otherwise.): (1) Is an external audit a compulsory obligation for banks? (2) Are specific requirements for the extent or nature of the audit spelled out? (3) Are auditors licensed or certified? (4) Do supervisors get a copy of the auditor’s report? (5) Does the supervisory agency have the right to meet with external auditors to discuss their report without the approval of the bank? (6) Are auditors required by law to communicate directly to the supervisory agency any presumed involvement of bank directors or senior managers in illicit activities, fraud, or insider abuse? (7) Can supervisors take legal action against external auditors for negligence? Higher values indicate greater strength of external audit.” Barth et al., (2006).
External Monitoring	“The sum of assigned values of the questions as below (by default, 1 if it equals “yes” and 0 otherwise.): (1) What percentage of the top ten banks are rated by international credit rating agencies (e.g., Moody’s, Standard and Poor)? (1 if it equals 100%; 0 otherwise.) (2) How many of the top ten banks are rated by domestic credit rating agencies? (1 if it equals 100%; 0 otherwise.) (3) a. Is there an explicit deposit insurance protection system? b. Were depositors wholly compensated (to the extent of legal protection) the last time a bank failed? (1 if a =0 and/or b=0, 0 otherwise.) (4) a. Is subordinated debt allowable as part of capital? b. Is subordinated debt required as part of capital? (1 if a or b equals “yes”) (5) Are bank regulators/supervisors required to make public formal enforcement actions, which include cease and desist orders and written agreements between a bank regulatory/supervisory body and a banking organization? Higher values indicate greater external monitoring.” Barth et al., (2006).
Direct Supervision	“The sum of assigned values of the questions as below (by default, 1 if it equals “yes” and 0 otherwise.): (1) Can the supervisory authority force a bank to change its internal organizational structure? (2) Are off-balance sheet items disclosed to supervisors? (3) Can the supervisory agency order the bank’s directors or management to constitute provisions to cover actual or potential losses? (4) Can the supervisory agency suspend the directors’ decision to distribute dividends? (5) Can the supervisory agency suspend the directors’ decision to distribute Bonuses? (6) Can the supervisory agency suspend the directors’ decision to distribute management fees? (7) Who can legally declare -

---

	<p>such that this declaration supersedes the some of the rights of shareholders - that a bank is insolvent: bank supervisor, court, deposit insurance agency, bank restructuring, asset management agency or other. (bank supervisor = 1; deposit insurance agency=0.5; bank restructuring or asset management agency=0.5; 0 otherwise.) (8) According to the Banking Law, who has authority to intervene – that is, suspend some or all ownership rights- a problem bank? Bank supervisor, court, deposits insurance agency, bank restructuring, asset management agency or other. (bank supervisor = 1; deposit insurance agency=0.5; bank restructuring or asset management agency=0.5; 0 otherwise.) (9) Regarding bank restructuring and reorganization, can the supervisory agency or any other government agency supersede shareholder rights? Bank supervisor, court, deposits insurance agency, bank restructuring, asset management agency or other. (Bank supervisor = 1; deposit insurance agency=0.5; bank restructuring or asset management agency=0.5; 0 otherwise.) (10) Regarding bank restructuring and reorganization, can the supervisory agency or any other government agency remove and replace management? Bank supervisor, court, deposits insurance agency, bank restructuring, asset management agency or other. (Bank supervisor = 1; deposit insurance agency=0.5; bank restructuring or asset management agency=0.5; 0 otherwise.) (11) Regarding bank restructuring and reorganization, can the supervisory agency or any other government agency remove and replace directors? Bank supervisor, court, deposits insurance agency, bank restructuring, asset management agency or other. (bank supervisor = 1; deposit insurance agency=0.5; bank restructuring or asset management agency=0.5; 0 otherwise.) Higher values indicate greater direct supervision.” Barth et al., (2006).</p>
Enforcement	External Audit + External Monitoring + Direct Supervision
External Audit & Direct Supervision	External Audit + Direct Supervision
<b>Control variables</b>	
Accounting Standards	“The assigned values of the questions as below (by default, 1 if it equals “yes” and 0 otherwise.): Are accounting practices for banks in accordance with International Accounting Standards or U.S. Generally Accepted Accounting Standards? Higher values indicate better accounting standard.” Barth et al., (2006).
Activity Restriction	“The sum of assigned values of the questions about whether banks can engage in securities, insurance, and real estate activities. Unrestricted = 1 = full range of activities can be conducted directly in the bank; Permitted = 2 = full range of activities can be conducted, but some or all must be conducted in subsidiaries; Restricted = 3 = less than full range of activities can be conducted in the bank or subsidiaries; and Prohibited = 4 = the activity cannot be conducted in either the bank or subsidiaries. Higher values indicate greater restrictiveness.” Barth et al., (2006).
Capital Stringency	“The sum of dummy variables or assigned values of questions (by default, 1 if it equals “yes” and 0 otherwise.): (1) Is the minimum capital-asset ratio requirement risk weighted in line with the Basel I guidelines? (2) Does the minimum ratio vary as a function of an individual bank’s credit risk? (3) Does the minimum ratio vary as a function of market risk? (4) Before minimum capital adequacy is determined, which of the following are deducted from the book value of capital? Market value of loan losses not realized in accounting books? (5) Unrealized losses in securities portfolios? (6) Unrealized foreign exchange losses? (7) Is the fraction of revaluation gains allowed as part of capital less than 0.75? (8) Are the sources of funds to be used as capital verified by the regulatory/supervisory authorities? (9) Can the initial disbursement of subsequent injections of capital be done with assets other than cash or government securities? (1 if it equals “no” and 0 otherwise.) (10) Can initial disbursement of capital be done with borrowed funds? (1 if it equals “no” and 0 otherwise.)” Barth et al. (2006).

---

---

Democracy Quality	Revised combined polity score.
GDP Per Capita	Log of GDP per capita.
GDP Growth	GDP growth.
Share Turnover	The difference in the average monthly bank stock share turnover between the current year and the prior year. The monthly bank stock share turnover is constructed as the monthly bank stock trading volume divided by the number of stock shares outstanding.
Deviation of Return	The standard deviation of bank-specific weekly returns in a given year.
Mean of Return	The mean of bank-specific weekly returns in a given year.
Bank Total Assets	Log (total assets).
STD ROA	The standard deviation of ROAs for a bank over the prior five-year period.
Nonperforming Loan	Total problem loans divided by total assets.
Analyst	The number of analysts with earnings forecasts for a bank.

---

Panel A of Table 5 presents the individual impacts of accounting regulations. The variable Accounting Regulation consists of the following six World Bank survey questions: “(SQ1) Does accrued, though unpaid interest/principal enter the income statement while the loan is still performing? (SQ2) Are financial institutions required to produce consolidated accounts covering all bank and any nonbank financial subsidiaries? (SQ3) Are off-balance sheet items disclosed to the public? (SQ4) Must banks disclose their risk management procedures to the public? (SQ5) Are bank directors legally liable if information disclosed is erroneous or misleading? (SQ6) Does accrued, though unpaid interest/principal enter the income statement while the loan is still nonperforming? (1 if it is No; 0 otherwise.)” Barth et al., (2006).

We present the variable definitions in Table 1. We report P-values in parentheses. We use \*, \*\*, \*\*\* to indicate 10%, 5%, and 1% significance levels, respectively.
